The exhaust chambers should be integrated into the generator design, and the air ducts should be designed to ensure that no gas or air can infiltrate the generator room.

A generator exhaust system is designed to safely remove combustion gases produced by the generator's engine and release them away from the building, typically through a wall or roof termination.

The exhaust system is equipped with a bypass valve and a bypass stack which provides a safety-related exhaust path in the event that a system failure downstream restricts the exhaust flow.
