Large-scale underground energy storage technology uses underground spaces for renewable energy storage, conversion and usage. It forms the technological basis of achieving carbon peaking and carbon neutrality goals.

Which geological structures are suitable for underground storage?

are equally suitable for the storage of hydrogen, natural gas, and carbon dioxide. At present, four types of geological structures can, in principle, be considered technically viable for the underground storage of hydrogen, natural gas, and carbon dioxide: salt caverns, rock caverns, deep aquifers, and depleted hydrocarbon

Which subsurface structures are suitable for gas storage?

gas, hydrogen, and carbon dioxide, focusing on the four key subsurface structures. It finds that not all formations are equally suitable for all gases: salt and rock caverns and smaller depleted fields are optimal for hydrogen and natural gas storage, while large-scale aquifers and depleted hydrocarbon

Surface-level lithium-ion installations now occupy spaces equivalent to 650 football fields daily, yet still struggle with thermal runaway risks. This spatial paradox highlights why underground ...
