Do solar cells bias themselves?

Solar cells are photovoltaic devices: they develop a photo-voltage when illuminated. In this sense they bias themselves. But that is a very confusing way of thinking about the as components in an electrical circuit. To get useful power out of a solar cell you must apply forward bias.

Why do solar cells have a reverse bias?

This is because under illumination, there is optical generation going on in the solar cell IN ADDITION to the thermal generation of carriers. Under a reverse bias, the minority electrons go from p to n-type and minority holes go from n to p-type.

What is solar cell voltage?

Solar cell voltage refers to the electrical potential difference produced by solar cells when they convert light energy into electricity. This conversion process is governed by the photovoltaic effect, where photons striking the solar cell generate electron-hole pairs.

Why does a solar cell have a negative current?

But, because of optical generation, there's more of these carriers flowing and so the reverse current is higher. Now another confusion of mine is why under a weak forward bias, the I-V curve for an illuminated solar cell still shows that the current is negative (i.e. the 4th quadrant of the I-V curve for an illuminated solar cell).
